

### Which Side Is UP?

When working with dichroic glass you will need to know which side is coated so here's a simple test method for you to employ. Take a toothpick and gently touch the surface of the glass. If you can see the reflected image actually touching the surface, you are touching the coated surface. If you see the image of the toothpick with a small space (approx. 1/16th of an inch) between the tip of the pick and the glass, you are touching the non-coated side. The dichroic coating is susceptible to scratching until it has been fused, therefore one should use care when handling the glass and always cut on the NON-coated side.
